The F-method and a branching problem for
generalized Verma modules associated to
\((\text{Lie } G_2, \text{so}(7))\)

Todor Milev and Petr Somberg

Abstract

The branching problem for a couple of non-compatible Lie algebras
and their parabolic subalgebras applied to generalized Verma modules
was recently discussed in [15]. In the present article, we employ the re-
cently developed F-method, [10], [11] to the couple of non-compatible Lie
algebras (Lie \( G_2, \text{so}(7) \)), and generalized conformal so(7)-Verma modules
of scalar type. As a result, we classify the Lie \( G_2 \cap \mathfrak{p}' \)-singular vectors for
this class of so(7)-modules.

Key words: Generalized Verma modules, Conformal geometry in dimension
5, Exceptional Lie algebra Lie \( G_2 \), F-method, Branching problem.

1 Introduction and Motivation

The subject of our article has its motivation in the Lie theory problem of branch-
ing rules for finite dimensional simple Lie algebras and composition structure of
generalized Verma modules, and dually in the geometrical problem related to the
construction of invariant differential operators in parabolic invariant theories.

We assume that \( \mathfrak{g}, \mathfrak{g}' \) are complex semisimple Lie algebras and \( i : \mathfrak{g}' \hookrightarrow \mathfrak{g} \)
is an injective homomorphism. Then \( i(\mathfrak{g}') \) is (complex) reductive in \( \mathfrak{g} \) and we
can choose Borel subalgebras \( \mathfrak{b}' \subset \mathfrak{g}' \) and \( \mathfrak{b} \subset \mathfrak{g} \) such that \( i(\mathfrak{b}') \subset \mathfrak{b} \). Let
\( \mathfrak{p} \supset \mathfrak{b} \) be a parabolic subalgebra of \( \mathfrak{g} \). Let \( M^\mathfrak{g}_\mathfrak{p}(\mathcal{V}_\lambda) \) be the generalized Verma
\( \mathfrak{g} \)-module induced from the irreducible finite dimensional \( \mathfrak{p} \)-module \( \mathcal{V}_\lambda \) with
highest weight \( \lambda \). We define the branching problem for \( M^\mathfrak{g}_\mathfrak{p}(\mathcal{V}_\lambda) \) over \( \mathfrak{g}' \) to be
the problem of finding all \( \mathfrak{b}' \)-singular vectors in \( M^\mathfrak{g}_\mathfrak{p}(\mathcal{V}_\lambda) \), that is, the set of all
vectors annihilated by image of the nilradical of \( \mathfrak{b}' \) on which the image of the
Cartan subalgebra of \( \mathfrak{b}' \) has diagonal action.

In the recent article [15], under certain technical assumptions, we proved that
\( M^\mathfrak{g}_\mathfrak{p}(\mathcal{V}_\lambda) \) has (finite or infinite) Jordan-Hölder series over \( \mathfrak{g}' \), and enumerated the
\( \mathfrak{b}' \)-highest weights \( \mu \) appearing in the series. We also computed the dimension
\( m(\mu, \lambda) \) of the vector space of \( \mathfrak{b}' \)-highest weights of weight \( \mu \) as a function of \( \mu \)
these invariant differential operators, in particular their curved extensions as a natural problem in conformal geometry of dimension 5 (note that so\(\frac{3}{2}\))

versusconstructed in the article determine invariant differential operators acting between induced representations of

\(\text{Ind}_{\mathfrak{g}}^\mathfrak{g} (\mathbb{V}_\lambda)^*\) is its dual, and \(\text{Ind}_{\mathfrak{g}}^\mathfrak{g}\) denotes induction from \(\mathfrak{p}\) to \(\mathfrak{g}\). As a consequence, the singular vectors constructed in the article determine invariant differential operators acting between induced representations of \(i(G')\). It is quite interesting to construct these invariant differential operators, in particular their curved extensions as lifts to homomorphisms of semiholonomic generalized Verma modules.

Our motivation for the particular example Lie \(G_2 \hookrightarrow so(7)\) comes from a natural problem in conformal geometry of dimension 5 (note that so\(\frac{3}{2}\)) is the complexification of the conformal Lie algebra in dimension 5), see \[4\] and references therein. A geometrical characterization of the reduction of the structure
group with Lie algebra $so(7)$ down to Lie $G_2$ for a given inducing representation $V_\lambda$ is then given by invariant differential operators acting on sections of the associated vector bundles, intertwined by actions of $so(7)$ and Lie $G_2$.

The structure of the article is as follows. In Section 2 we recall basic conventions on $so(7)$, Lie $G_2$, $i(Lie \ G_2)$ and the structure of their parabolic subalgebras relative to the embedding $i$. In Section 3, we use \[11\] to transform the problem of finding differential invariants for $(so(7), Lie \ G_2)$, $\forall \lambda$ into an algebraic question about homomorphisms between generalized Verma modules, corresponding to solutions of the branching problem. In Section 4 we fix the conformal parabolic subalgebra $p \subset so(7)$ and the parabolic subalgebra $p' \subset Lie \ G_2$ not compatible with $(g,p)$, $p' = i(g') \cap p$. We further fix the highest weight to be $\lambda \in \mathfrak{h}_S$ (here we use $\lambda$ as a scalar). We then apply the distribution Fourier transform (the “F-method”) developed in [10], [11] to obtain our main result Theorem 4.2.

## 2 Branching problem and (non-compatible) parabolic subalgebras for the pair $Lie \ G_2 \overset{i}{\hookrightarrow} so(7)$

In the present Section we introduce the Lie theoretic conventions for the complex Lie algebra $so(7)$, exceptional Lie algebra Lie $G_2$, and Levi resp. parabolic subalgebras $p$ of $so(7)$ relative to parabolic subalgebras $i(p')$ of $i(Lie \ G_2)$. These will be used in the subsequent Section 3, where we employ the F-method. For more detailed review, cf. [15].

We start by fixing a Chevalley-Weyl basis of the Lie algebra $so(2n + 1)$. Let the defining vector space $V$ of $so(2n + 1)$ have a basis $e_1, \ldots, e_n, e_0, e_{-1}, \ldots, e_{-n}$, where the defining symmetric bilinear form $B$ of $so(2n+1)$ is given by $B(e_i, e_j) := 0$, $i \neq j$, $B(e_i, e_{-i}) := 1$, $B(e_i, e_0) := 0$, $B(e_0, e_0) := 1$, or alternatively defined as an element of $S^2(V^*)$,

$$B := \sum_{i=-n}^{n} e_i^* \otimes e_{-i} = (e_0^*)^2 + 2 \sum_{i=1}^{n} e_i^* e_{-i}, \quad (2)$$

under the identification $v^* w^* := \frac{1}{2!} (v^* \otimes w^* + w^* \otimes v^*)$.

In the basis $e_1, \ldots, e_n, e_0, e_{-1}, \ldots, e_{-n}$, the matrices of the elements of $so(2n + 1)$ are of the form

$$\begin{pmatrix}
A & v_1 & \vdots & C = -C^T \\
-1 & v_n & & \\
& 0 & & -v_1 \ldots -v_n \\
\end{pmatrix},$$

$$D = -D^T$$

i.e., all matrices $C$ such that $A^T B + B A = 0$. We fix $e_1^*, \ldots, e_n^*, e_0^*, e_{-1}^*, \ldots, e_{-n}^*$ to be basis of $V^*$ dual to $e_1, \ldots, e_n, e_0, e_{-1}, \ldots, e_{-n}$. We identify elements of $End(V)$
with elements of $V \otimes V^*$. In turn, we identify elements of $\text{End}(V)$ with their matrices in the basis $e_1, \ldots, e_n, e_0, e_{-1}, \ldots, e_{-n}$.

Fix the Cartan subalgebra $\mathfrak{h}$ of $\text{so}(2n+1)$ to be the subalgebra of diagonal matrices, i.e., the subalgebra spanned by the vectors $e_i \otimes e_i^* - e_{-i} \otimes e_{-i}^*$. Then the basis vectors $e_1, \ldots, e_n, e_0, e_{-1}, \ldots, e_{-n}$ are a basis for the $\mathfrak{h}$-weight vector decomposition of $V$. Let the $\mathfrak{h}$-weight of $e_i, i > 0$, be $\varepsilon_i$. Then the $\mathfrak{h}$-weight of $e_{-i}, i > 0$ is $-\varepsilon_i$, and an $\mathfrak{h}$-weight decomposition of $\text{so}(2n+1)$ is given by the elements $g_{\varepsilon_i} := e_i \otimes e_i^* - e_{-i} \otimes e_{-i}^*$, $g_{\varepsilon_i \pm \varepsilon_i} := e_i \otimes e_i^* \pm e_{-i} \otimes e_{-i}^*$ and $g_{\varepsilon_i \varepsilon_i} := \sqrt{2}(e_i \otimes e_0 - e_0 \otimes e_i)$, where $i, j > 0$.

Define the symmetric bilinear form $\langle \cdot, \cdot \rangle_{\mathfrak{h}^*}$ on $\mathfrak{h}^*$ by $\langle \varepsilon_i, \varepsilon_j \rangle_{\mathfrak{h}^*} = 1$ if $i = j$ and zero otherwise.

The root system of $\text{so}(2n+1)$ with respect to $\mathfrak{h}$ is given by $\Delta(\mathfrak{g}) := \Delta^+(\mathfrak{g}) \cup \Delta^-(\mathfrak{g})$, where we define

$$\Delta^+(\mathfrak{g}) := \{ \varepsilon_i \pm \varepsilon_j | 1 \leq i < j \leq n \} \cup \{ \varepsilon_i | 1 \leq i \leq n \} \quad (3)$$

and $\Delta^-(\mathfrak{g}) := -\Delta^+(\mathfrak{g})$. We fix the Borel subalgebra $\mathfrak{b}$ of $\text{so}(2n+1)$ to be the subalgebra spanned by $\mathfrak{h}$ and the elements $g_\alpha, \alpha \in \Delta^+(\mathfrak{g})$. The simple positive roots corresponding to $\mathfrak{h}$ are then given by

$$\eta_1 := \varepsilon_1 - \varepsilon_2, \ldots, \eta_{n-1} := \varepsilon_{n-1} - \varepsilon_n, \eta_n := \varepsilon_n.$$ 

For the remainder of this Section we fix the odd orthogonal Lie algebra to be $\text{so}(7)$. We order the 18 roots of $\text{so}(7)$ in graded lexicographic order with respect to their simple basis coordinates. We then label the negative roots by the indices $-9, \ldots, -1$ and the positive roots by the indices $1, \ldots, 9$. Finally, we abbreviate the Chevalley-Weyl generator $g_\alpha \in \text{so}(7)$ by $g_i$, where $i$ is the label of the corresponding root. For example, $g_{\varepsilon_1} = g_{\varepsilon_1 - \varepsilon_2}, g_{\varepsilon_2} = g_{\varepsilon_3 - \varepsilon_4}, g_{\varepsilon_3} = g_{\varepsilon_5 - \varepsilon_6}, g_{\varepsilon_4} = g_{\varepsilon_6 - \varepsilon_7}$ are the simple positive and negative generators, the element $g_{-\varepsilon_1} = g_{-\varepsilon_1 + \varepsilon_2}$ is the Chevalley-Weyl generator corresponding to the lowest root, and so on. We furthermore set $h_1 := [g_1, g_{-1}], h_2 := [g_2, g_{-2}], h_3 := 1/2[g_3, g_{-3}]$.

Let now $\mathfrak{g}' = \text{Lie} G_2$. One way of defining the positive root system of $\text{Lie} G_2$ is by setting it to be the set of vectors

$$\Delta(\mathfrak{g}') := \{ \pm(1,0), \pm(0,1), \pm(1,1), \pm(1,2), \pm(1,3), \pm(2,3) \}. \quad (4)$$

We set $\alpha_1 := (1, 0)$ and $\alpha_2 := (0, 1)$. We fix a bilinear form $\langle \cdot, \cdot \rangle_{\mathfrak{g}'}$ on $\mathfrak{g}'$, proportional to the one induced by Killing form by setting

$$\begin{pmatrix} \langle \alpha_1, \alpha_1 \rangle_{\mathfrak{g}'} & \langle \alpha_1, \alpha_2 \rangle_{\mathfrak{g}'} \\ \langle \alpha_2, \alpha_1 \rangle_{\mathfrak{g}'} & \langle \alpha_2, \alpha_2 \rangle_{\mathfrak{g}'} \end{pmatrix} := \begin{pmatrix} 2 & -3 \\ -3 & 6 \end{pmatrix}. \quad (5)$$

In an $\langle \cdot, \cdot \rangle_{\mathfrak{g}'}$-orthogonal basis the root system of $\text{Lie} G_2$ is often drawn as

\[\begin{array}{c}
\alpha_1 \\
\alpha_2
\end{array}\]
Similarly to the $so(7)$ case, we order the 12 roots of Lie $G_2$ in the graded lexicographic order with respect to their simple basis coordinates, and label the roots with the indices $-6, \ldots, -1, 1, \ldots, 6$. We fix a basis for the Lie algebra Lie $G_2$ by giving a set of Chevalley-Weyl generators $g'_i$, $i \in \{\pm 1, \ldots, \pm 6\}$, and by setting $h'_1 := [g'_1, g'_{-1}], h'_2 := 3[g'_2, g'_{-2}]$. Just as in the $so(7)$ case, we ask that the generator $g'_i$ correspond to the root space labelled by $\pm i$.

All embeddings Lie $G_2 \hookrightarrow so(7)$ are conjugate over $\mathbb{C}$. One such embedding is given via

$$i(g'_\pm 2) := g_\pm 2, \quad i(g'_{\pm 1}) := g_{\pm 1} + g_{\pm 3}.$$  

As $g'_{\pm 1}, g'_{\pm 2}$ generate Lie $G_2$, the preceding data determines the map $i$ and one can directly check it is a Lie algebra homomorphism. Alternatively, we can use $i(g'_{\pm 1}), i(g'_{\pm 2})$ to generate a Lie subalgebra of $so(7)$, verify that this subalgebra is indeed 14-dimensional and simple, and finally use this 14-dimensional image to compute the structure constants of Lie $G_2$.

We denote by $\omega_1 := \epsilon_1$, $\omega_2 := \epsilon_1 + \epsilon_2$ and $\omega_3 := \frac{1}{2}(\epsilon_1 + \epsilon_2 + \epsilon_3)$ the fundamental weights of $so(7)$ and by $\psi_1 := 2\alpha_1 + \alpha_2$, $\psi_2 := 3\alpha_1 + 2\alpha_2$ the fundamental weights of Lie $G_2$.

Let $pr : h^* \to b'^*$ be the map naturally induced by $i$. Then

$$pr(\varepsilon_1 - \varepsilon_2) = pr(\varepsilon_3) = \alpha_1, \quad pr(\varepsilon_2 - \varepsilon_3) = \alpha_2,$$

or equivalently

$$pr(\omega_1) = pr(\omega_3) = \psi_1, \quad pr(\omega_2) = \psi_2.$$  

Conversely, $\iota : b'^* \to b^*$ is the map

$$\iota(\alpha_2) = 3\eta_2 = 3\varepsilon_2 - 3\varepsilon_3, \quad \iota(\alpha_1) = \eta_1 + 2\eta_3 = \varepsilon_1 - \varepsilon_2 + 2\varepsilon_3.$$  

We recall from [15] that the pairwise inclusions between the parabolic subalgebras of $so(7)$ and the embeddings of the parabolic subalgebras of Lie $G_2$ are given as follows.

**Lemma 2.1** For the pair $G_2 \hookrightarrow so(7)$, let $h, b, p, h', b', p'$ denote respectively Cartan, Borel and parabolic subalgebras with the assumptions that $i(b') \subset h \subset b$, $i(b') \subset b \subset p$, $b' \subset p'$. Then we have the following inclusion diagram for all
possible values of \( p, p' \).

\[
\begin{array}{c}
p_{(0,0,0)} \simeq \text{so}(7) \\
p_{(1,0,0)} \quad p_{(0,1,0)} \quad p_{(0,0,1)} \quad p'_{(0,0)} \simeq \text{Lie} G_2 \\
p_{(1,1,0)} \quad p_{(1,0,1)} \quad p_{(0,1,1)} \\
p_{(1,1,1)} \simeq \mathfrak{b} \quad p'_{(1,0)} \quad p'_{(0,1)} \\
p'_{(1,1)} \simeq \mathfrak{b}'
\end{array}
\]

If a path of arrows exists from one node of the diagram to the other, then the corresponding parabolic subalgebras lie inside one another. If in the diagram a direct arrow exists from a parabolic subalgebra \( p' \) of \( \text{Lie} G_2 \) to a parabolic subalgebra \( \mathfrak{p} \) of \( \text{so}(7) \), then \( p' = i^{-1}(i'(\mathfrak{g}) \cap \mathfrak{p}) \).

The structure of \( \text{so}(7) \) as a module over the Levi part of parabolic subalgebras of \( \text{Lie} G_2 \) is described in detail in [15, Lemma 5.2] (the lemma is too large to recall here) and we will implicitly use it throughout Section 4.

Note that in the special case of conformal parabolic subalgebra \( \mathfrak{p} \supset \mathfrak{b} \supset \mathfrak{h} \) of \( \text{so}(7) \) and \( p' \) of \( i(\text{Lie} G_2) \) given by \( p' = i(\mathfrak{g}) \cap \mathfrak{p} \) are not compatible.

### 3 Branching problem and the F-method (algebraic distribution Fourier transformation)

In the present Section we briefly review the F-method developed in [10], [11]. It is based on the analytical tool of algebraic Fourier transformation on the commutative nilradical \( \mathfrak{n} \) of \( \mathfrak{p} \), which allows to find singular vectors in generalized Verma modules exploiting the algebraic Fourier transform and classical invariant theory. The method converts a problem in the universal enveloping algebra of a Lie algebra into a system of partial or ordinary special differential equations acting on a polynomial ring. In examples known to us, the conversion to partial differential equations yields a lot more tractable problem than the starting universal enveloping algebra one.

Let \( \tilde{G} \) be a connected real reductive Lie group with the Lie algebra \( \tilde{\mathfrak{g}} \), \( \tilde{\mathfrak{p}} \subset \tilde{\mathfrak{g}} \) a parabolic subgroup and \( \mathfrak{p} \) its Lie algebra, \( \mathfrak{p} = \tilde{\mathfrak{p}} \oplus \tilde{\mathfrak{n}} \) the Levi decomposition of \( \tilde{\mathfrak{p}} \) and \( \tilde{\mathfrak{n}}_+ \) its opposite nilradical, \( \tilde{\mathfrak{g}} = \tilde{\mathfrak{n}}_+ \oplus \tilde{\mathfrak{p}} \). The corresponding Lie groups
are denoted \( \tilde{N}_-, \tilde{L}, \tilde{N} \). Let \( p \) denote the fibration \( \tilde{G} \to \tilde{G}/\tilde{P} \) and let \( \tilde{M} := p(\tilde{N}_- \cdot \tilde{P}) \) denote the big Schubert cell of \( \tilde{G}/\tilde{P} \). Then the exponential map

\[
\tilde{n}_- \to \tilde{M}, \quad X \mapsto \exp(X) \cdot o \in \tilde{G}/\tilde{P}, \quad o := e \cdot \tilde{P} \in \tilde{G}/\tilde{P}, \quad e \in \tilde{G}.
\]
gives the canonical identification of the vector space \( \tilde{n}_- \) with \( \tilde{M} \).

Given a complex finite dimensional \( \tilde{P} \)-module \( V \) (in the present Section we do not indicate explicitly its highest weight), let \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \) denote the space of smooth sections of the homogeneous vector bundle \( \tilde{G} \times \tilde{P} V \to \tilde{G}/\tilde{P} \), i.e.,

\[
\text{Ind}^{\tilde{G}}_{\tilde{P}}(V) = C^\infty(\tilde{G}, V)^\tilde{P} := \{ f \in C^\infty(\tilde{G}, V)| f(g \cdot p) = p^{-1} \cdot f(g), \quad g \in \tilde{G}, p \in \tilde{P} \}.
\]

Let \( \tilde{\pi} \) denote the induced representation of \( \tilde{G} \) on \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \).

Let \( \mathcal{U}(\tilde{g}_C) \) denote the universal enveloping algebra of the complexified Lie algebra \( \tilde{g}_C \). Let \( V^\vee \) be the dual (contragredient) representation to \( V \). The generalized Verma module \( M^\tilde{g}_p(V^\vee) \) is defined by

\[
M^\tilde{g}_p(V^\vee) := \mathcal{U}(\tilde{g}) \otimes_{\mathcal{U}(\tilde{g})} V^\vee,
\]

and there is a \( (\tilde{g}, \tilde{P}) \)-invariant natural pairing between \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \) and \( M^\tilde{g}_p(V^\vee) \), described as follows. Let \( \mathcal{D}'(\tilde{G}/\tilde{P}) \otimes V^\vee \) be the space of all distributions on \( \tilde{G}/\tilde{P} \) with values in \( V^\vee \). The evaluation defines a canonical equivariant pairing between \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \) and \( \mathcal{D}'(\tilde{G}/\tilde{P}) \otimes V^\vee \), and this restricts to the pairing

\[
\text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \times \mathcal{D}'(\tilde{G}/\tilde{P}) \otimes V^\vee \to \mathbb{C}, \tag{8}
\]

where \( \mathcal{D}'(\tilde{G}/\tilde{P}) \otimes V^\vee \) denotes the space of distributions supported at the base point \( o \in \tilde{G}/\tilde{P} \). As shown in [1], the space \( \mathcal{D}'(\tilde{G}/\tilde{P}) \otimes V^\vee \) can be identified, as an \( \mathcal{U}(\tilde{g}) \)-module, with the generalized Verma module \( M^\tilde{g}_p(V^\vee) \).

Moreover, given two inducing representations \( V \) and \( V' \) of \( \tilde{P} \), the space of \( \tilde{G} \)-equivariant differential operators from \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \) to \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V') \) is isomorphic to the space of \( (\tilde{g}, \tilde{P}) \)-homomorphisms between \( M^\tilde{g}_p(V^\vee) \) and \( M^\tilde{g}_p(V'^\vee) \). The homomorphisms of generalized Verma modules are determined by their singular vectors, and the F-method translates the problem of finding singular vectors to the study of distributions on \( \tilde{G}/\tilde{P} \) supported at the origin, and consequently to the problem of finding the solution space for a system of partial differential equations acting on polynomials \( \text{Pol}(\tilde{n}) \) on \( \tilde{n} \).

The representation \( \tilde{\pi} \) of \( \tilde{G} \) on \( \text{Ind}^{\tilde{G}}_{\tilde{P}}(V) \) has the infinitesimal representation \( d\tilde{\pi} \) of \( \tilde{g}_C \). In the non-compact case, \( \tilde{\pi} \) acts on functions on the big Schubert cell \( \tilde{n}_- \simeq \tilde{M} \subset \tilde{G}/\tilde{P} \) with values in \( V \). The latter representation space can be identified via the exponential map with \( C^\infty(\tilde{n}_-, V) \). The action \( d\tilde{\pi}(Z) \) of elements \( Z \in \tilde{n} \) on \( C^\infty(\tilde{n}_-, V) \) is realized by vector fields on \( \tilde{n}_- \) with coefficients in \( \text{Pol}(\tilde{n}_- \otimes \text{End} V) \), see [12].
By the Poincaré–Birkhoff–Witt theorem, the generalized Verma module $M^p_{\tilde{\mathfrak{g}}}(V^\vee)$ is isomorphic to $U(\tilde{n}_- ) \otimes V^\vee \simeq \text{Diff}_{\tilde{\mathfrak{g}}}(\tilde{n}_-) \otimes V^\vee$ as an $\tilde{\mathfrak{l}}$-module. In the special case when $\tilde{n}_-$ is commutative, $\text{Diff}_{\tilde{\mathfrak{g}}}(\tilde{n}_-) \otimes V^\vee$, and is necessarily finite-dimensional. However for $\tilde{n}_-$, the set $\text{Diff}_{\tilde{\mathfrak{g}}}(\tilde{n}_-) \otimes V^\vee$ is commutative, $\text{Diff}_{\tilde{\mathfrak{g}}}(\tilde{n}_-) \otimes V^\vee$ with the space $\text{Pol}(\tilde{\mathfrak{g}}) \otimes V^\vee$, and the action $d\tilde{\pi}^\vee$ of $\tilde{\mathfrak{g}}$ on $\text{Diff}_{\tilde{\mathfrak{g}}}(\tilde{n}_-) \otimes V^\vee$ translates to the action $(d\tilde{\pi}^\vee)^F$ of $\tilde{\mathfrak{g}}$ on $\text{Pol}(\tilde{\mathfrak{g}}) \otimes V^\vee$ and is realized again by differential operators with values in $\text{End}(V^\vee)$. The explicit form of $(d\tilde{\pi}^\vee)^F(X)$ is easy to compute by Fourier transform from the explicit form of $d\tilde{\pi}^\vee$.

The previous framework can be applied to two any two couples $\tilde{\mathfrak{g}} \subset \tilde{G} \subset \check{G}$ and $\tilde{\mathfrak{g}}' \subset \check{G}'$ of Lie groups compatible in the sense that $\check{G}' \subset \check{G}$ is a reductive subgroup of $G$ and $\tilde{\mathfrak{g}}' = \tilde{\mathfrak{g}} \cap \check{G}'$ is a parabolic subgroup of $\check{G}'$. The Lie algebras of $\check{G}'$, $\check{G}$ are denoted by $\tilde{\mathfrak{g}}'$, $\tilde{\mathfrak{g}}$. In this case, $\tilde{n}' := \tilde{n} \cap \tilde{\mathfrak{g}}'$ is the nilradical of $\tilde{\mathfrak{g}}'$, and $\check{L}' = \tilde{L} \cap \check{G}'$ is the Levi subgroup of $\check{G}'$. We are interested in the branching problem for generalized Verma modules $M^p_{\tilde{\mathfrak{g}}} (V^\vee)$ over, $\tilde{\mathfrak{g}}$, i.e., in the structure of the restriction of $M^p_{\tilde{\mathfrak{g}}} (V^\vee)$ to $\tilde{\mathfrak{g}}$.

**Definition 3.1** Let $V$ be an irreducible $\check{\tilde{\mathfrak{g}}}$-module. Define the $\check{\mathfrak{l}}'$-module

$$M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee) := \{v \in M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)| d\check{\tilde{\pi}} (Z)v = 0 \text{ for all } Z \in \tilde{n}'\}.$$ (9)

The set $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ is a completely reducible $\check{\mathfrak{l}}'$-module. Note that for $\check{G} = \tilde{G}'$, $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ is necessarily finite-dimensional. However for $\check{G} \neq \tilde{G}'$, the set $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ will in general (but not necessarily, as illustrated in the next Section) be infinite dimensional. An irreducible $\check{\mathfrak{l}}'$-submodule $\mathcal{W}$ of $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)$ gives an injective $U(\check{\mathfrak{g}})$-homomorphism from $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ to $M^\check{\mathfrak{g}}_{\mathfrak{g}} (\mathcal{W})$. Dually, we get an equivariant differential operator acting from $\text{Ind}^\check{\mathfrak{g}}_{\mathfrak{g}} (\mathcal{W})$ to $\text{Ind}^\check{\mathfrak{g}}_{\mathfrak{g}} (\mathcal{W})$.

Using the F-method, the space of $\check{\mathfrak{l}}'$-singular vectors $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ is realized in the ring of polynomials on $\tilde{n}$ valued in $V^\vee$ and equipped with the action of $(d\tilde{\pi})^F$.

**Definition 3.2** We define

$$\text{Sol}(\mathfrak{g}, \check{\mathfrak{g}}', V^\vee) := \{f \in \text{Pol}(\tilde{n}) \otimes V^\vee| (d\tilde{\pi}^\vee)^F(Z)f = 0 \text{ for all } Z \in \tilde{n}'\}. $$ (10)

Then the inverse Fourier transform gives an $\check{\mathfrak{l}}'$-isomorphism

$$\text{Sol}(\check{\mathfrak{g}}, \check{\mathfrak{g}}'; V^\vee) \xrightarrow{\sim} M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'.$$ (11)

An explicit form of the action $(d\tilde{\pi}^\vee)^F(Z)$ leads to a system of differential equation for elements in $\text{Sol}$. The transition from $M^\check{\mathfrak{g}}_{\mathfrak{g}} (V^\vee)\tilde{n}'$ to $\text{Sol}$ transforms the
problem of computation of singular vectors in generalized Verma modules into a system of partial differential equations.

In the dual language of differential operators acting on principal series representation, the set of \( G' \)-intertwining differential operators from \( \text{Ind}_{\tilde{\mathfrak{p}}}^G(V) \) to \( \text{Ind}_{\tilde{\mathfrak{p}}}^G(V') \) is in bijective correspondence with the space of all \( (\tilde{g}', \tilde{P}') \)-homomorphisms from \( M_{\tilde{p}'}^G(\mathcal{V}) \) to \( M_{\tilde{p}'}^G(\mathcal{V}') \).

4 Lie \( G_2 \cap \mathfrak{p}' \)-singular vectors in the \( so(7) \)-generalized Verma modules of scalar type for the conformal parabolic subalgebra

In this subsection we determine the \( \tilde{\mathfrak{g}}' = i(Lie \ G_2) \cap \mathfrak{p} \)-singular vectors in the family of \( \tilde{\mathfrak{g}} = so(7) \) generalized Verma modules \( M_{\mathfrak{p}(1,0,0)}(\mathcal{C}_\lambda) \) induced from character \( \chi_\lambda : \tilde{\mathfrak{p}} \to \mathbb{C} \) of the weight \( \lambda \varepsilon_1 \) (\( \varepsilon_1 \) is the first fundamental weight of \( so(7) \)). In this way, the results computed in the present Section are analytic counterpart realized by F-method of the algebraic results developed in [15].

Let us denote by \( v_\lambda \) the highest weight vector of the generalized Verma \( so(7) \)-module \( M_{\mathfrak{p}(1,0,0)}(\mathcal{V}_\lambda) \). Notice that as \( i(h_{\alpha_1}) = 3h_{\varepsilon_2 - \varepsilon_3} \) and \( i(h_{\alpha_2}) = h_{\varepsilon_1 - \varepsilon_2} + 2h_{\varepsilon_3} \), the \( \mathfrak{b}' \)-weight of \( v_\lambda \) is \( \mu = \lambda(\alpha_1 + 2\alpha_2) \) because \( (\mu, \alpha_1) = 0, (\mu, \alpha_2) = \lambda \).

The opposite nilradical \( \mathfrak{n}_- \) associated to the parabolic subalgebra \( \mathfrak{p} \) is commutative,

\[
\mathcal{U}(\mathfrak{n}_-) \otimes \mathcal{V}' \simeq \text{Pol}\left( \frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_5} \right) \otimes \mathbb{C}_\lambda \simeq \text{Pol}\left( \frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_5} \right)
\]

and the variables \( \frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_5} \) denote the following \( so(7) \)-root spaces:

\[
\frac{\partial}{\partial x_1} := g_{-\varepsilon_1 + \varepsilon_2} = g_{-1}, \quad \frac{\partial}{\partial x_2} := g_{-\varepsilon_1 - \varepsilon_3} = g_{-8}, \quad \frac{\partial}{\partial x_3} := g_{-\varepsilon_2} = g_{-6}, \quad \frac{\partial}{\partial x_4} := g_{-\varepsilon_1 - \varepsilon_2} = g_{-9}.
\]

Here, we recall that \([x_i, \frac{\partial}{\partial x_j}] = -[\frac{\partial}{\partial x_j}, x_i] = \begin{cases} 0 & \text{if } i \neq j \\ -1 & \text{if } i = j \end{cases}\) is the adjoint action of the differential operator \( x_i \) on the differential operator \( \frac{\partial}{\partial x_i} \).

By Lemma 2.2, the simple part of the Levi factor of \( i(\tilde{\mathfrak{p}}) \) is isomorphic to \( sl(2) \) and its action on \( \mathfrak{n}_- \) can be extended to action on \( \mathcal{U}(\mathfrak{n}_-) \simeq S^*(\mathfrak{n}_-) \). The elements \( h := h_2, e := g_2, f := g_{-2} \) give the standard \( h, e, f \)-basis of \( sl(2) \), i.e., \([e, f] = h, [h, e] = 2e, [h, f] = -2f \). Then the action of \( h \) on \( \mathfrak{n}_- \) is the adjoint action of \( x_1 \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_2} - x_4 \frac{\partial}{\partial x_4} - x_5 \frac{\partial}{\partial x_5} \), the action of \( e \) is the adjoint action of \(-x_5 \frac{\partial}{\partial x_1} + x_4 \frac{\partial}{\partial x_2} \) and the action of \( f \) is the adjoint action of \(-x_1 \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_2} \).

We now proceed to generate all \( \mathfrak{t}' \)-invariant singular vectors in \( M_{\mathfrak{p}(1,0,0)}(\mathcal{C}_\lambda) \), i.e., the singular vectors that induce \( i(Lie \ G_2) \)-generalized Verma modules induced from character (scalar generalized Verma modules). To do that we need the following Lemma from classical invariant theory of reductive Lie algebras.
Lemma 4.1 Then the sl(2)-invariants of $S^*(n_-)$ are an associative algebra generated by the elements $u_1 := \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_4} + \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_5}$ and $u_2 = \frac{\partial}{\partial x_3}$.

Proof. Direct computation shows that $u_1, u_2$ are invariants. Alternatively, as the direct sum of two two-dimensional sl(2)-modules gives a natural embedding $sl(2) \hookrightarrow sl(2) \times sl(2)$, we can view $u_1$ as the invariant element induced by the defining symmetric bilinear form of $so(4) \cong sl(2) \times sl(2)$. Let the positive root of $sl(2)$ be $\eta$, and the multiplicity of the $sl(2)$-module with highest weight $t^u$ in $S^*(n_-)$ be $b(l, t)$. Denoting by $x, z$ a couple of formal variables, we have that $\sum_{l \in \mathbb{Z}_{>0}, t \in \mathbb{Z}_{>0}} b(l, t)(z^l x^t + z^l x^{-t})$ is the power series expansion of the rational function

$$(1 - x^{-2}) \frac{1}{(1 - zx)^2} \frac{1}{(1 - zx^{-1})^2} \frac{1}{(1 - z)}.$$ 

Direct computation shows that $b(l, t)$ equals $-1/2t^2 + 1 + 1/2l + 1/2l + 1/2t$ whenever $l + t$ is even and $-1/2t^2 + 1/2 + 1/2t + 1/2l + 1/2t$ whenever $l + t$ is odd, and $l, t$ satisfy the inequalities $l \geq t \geq 0$. Finally, substituting with $t = 0$, we get $b(l, 0) = 1 + l/2$ for even $l$ and $b(l, 0) = 1/2 + l/2$. For a fixed $l$, this is exactly the dimension of the vector space generated by the linearly independent invariants $u_1^l u_2^l \in S^*(n_-)$ with $r + 2q = l$, which completes the proof of our Lemma. □

It follows from the definition of embedding map $i$ that

$$\text{ad}(i(g_1)) = -x_2 \partial_4 + x_1 \partial_5,$$
$$\text{ad}(i(g_{-1})) = -x_4 \partial_2 + x_5 \partial_1,$$
$$\text{ad}(i(h_1)) = \text{ad}(i(g_1)) \text{ad}(i(g_{-1})) = x_1 \partial_{x_1} + x_2 \partial_{x_2} - x_4 \partial_{x_4} - x_5 \partial_{x_5},$$
$$\text{ad}(i(h_2)) = -3x_2 \partial_2 - x_3 \partial_3 + x_5 \partial_5 - 2x_1 \partial_1,$$

and therefore

$$\text{ad}(i(3h_1 + 2h_2)) = -x_1 \partial_{x_1} - 3x_2 \partial_{x_2} - 2x_3 \partial_{x_3} - 3x_4 \partial_{x_4} - x_5 \partial_{x_5}$$

represents the central element of the Levi factor $i(l')$. It induces a grading $\text{gr}$ on the Weyl algebra of $n_-$ in the variables

$$\{x_1, x_2, x_3, x_4, x_5, \frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}, \frac{\partial}{\partial x_5}\},$$

we have

$$\text{gr}(x_1) = -\text{gr}(\partial_1) = -1, \text{gr}(x_2) = -\text{gr}(\partial_2) = -3,$$
$$\text{gr}(x_3) = -\text{gr}(\partial_3) = -2, \text{gr}(x_4) = -\text{gr}(\partial_4) = -3,$$
$$\text{gr}(x_5) = -\text{gr}(\partial_5) = -1.$$ 

$^1\eta$ is of course the projection of long Lie $G_2$-root $\alpha_2 = \text{pr}(\varepsilon_2 - \varepsilon_3)$ from the dual of the two-dimensional Cartan subalgebra of Lie $G_2$ to the dual of the one-dimensional Cartan subalgebra of a long-root $sl(2)$-subalgebra of Lie $G_2$.}

10
i.e. the invariants $u_1 = \frac{\partial^2}{\partial x_1 \partial x_2} + \frac{\partial^2}{\partial x_3 \partial x_5}$ and $u_2 = (\frac{\partial^2}{\partial x_1 \partial x_5})^2$ are homogeneous with respect to the gr-grading.

Employing the distributive Fourier transform means that we pass to the polynomial ring $Pol[\xi_1, \ldots, \xi_5]$, where $\xi_i$ denote the Fourier images of $\frac{\partial}{\partial x_i}$, $i = 1, \ldots, 5$. In the image of the Fourier transform, the subalgebra of $t'_\mathfrak{g} = sl(2)$-invariants with respect to the Fourier dual representation is the polynomial ring $Pol[\xi_1 \xi_4 + \xi_2 \xi_5, \xi_3]$, cf. Lemma 4.1.

**Theorem 4.2** Let $v_\lambda$ be the highest weight vector of the $so(7)$-generalized Verma module $M_{s_0(7)}(\mathbb{C}, \lambda)$ induced from character $\chi_\lambda$, $\lambda \in \mathbb{C}$. Let $N \in \mathbb{N}$ be a positive integer and $A_i \in \mathbb{C}$, $i \in \mathbb{N}$ a collection of complex numbers such that at least one of them is non-zero.

1. A vector $u \cdot v_\lambda : (\text{Lie } G_2) \cap \mathfrak{p}$-singular vector ("singular vector of scalar type") of homogeneity $2N$ if and only if $\lambda = N - 5/2$ and $u = (2u_1 + u_2)^N = (2u_1 + u_2)^\lambda + 5/2$.

2. $M_{s_0(7)}(\mathbb{C}, \lambda)$ has no $i(\text{Lie } G_2) \cap \mathfrak{p}$-singular vector of homogeneity $2N + 1$.

3. A vector in $M_{s_0(7)}(\mathbb{C}, \lambda)$ is so(7) $\cap \mathfrak{p}$-singular if and only if it is the $i(\text{Lie } G_2) \cap \mathfrak{p}$-singular vector given in point 1.

**Proof**

1. By Lemma 4.1 and Section 2 a $\mathfrak{p}'$-singular vector of homogeneity $2N$ must be of the form $u := \sum_{k=0}^N A_k u_1^k u_2^{N-k}$.

First we determine the action of the second simple positive root $g_2$ in the Fourier dual representation $d\hat{\pi}(ad(i(g_2)))$, acting on $Pol[\xi_1, \ldots, \xi_5]$.

Let $n_i$ be non-negative integers. Then

$$i(g_2) \cdot (\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5} \cdot v_\lambda) =$$

$$= (-n_1^2 + n_1)\xi_1^{n_1-1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5} - n_2\xi_1^{n_1} \xi_2^{n_2-1} \xi_3^{n_3+1} \xi_4^{n_4} \xi_5^{n_5}$$

$$+n_1\lambda\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5} + (n_3 - N)\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4+1} \xi_5^{n_5}$$

$$+2n_3\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3-1} \xi_4^{n_4} \xi_5^{n_5+1} - n_1n_5\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5}$$

$$+n_2n_5\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4+1} \xi_5^{n_5-1} - n_1n_2\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5}$$

$$-n_1n_3\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5}) \cdot v_\lambda$$

$$= (-\xi_1 \partial_{\xi_1}^{2} - \xi_3 \partial_{\xi_3} + \lambda \partial_{\xi_1} + \xi_4 \partial_{\xi_2} + 2\xi_5 \partial_{\xi_3} - \xi_5 \partial_{\xi_1} \partial_{\xi_2} + \xi_4 \partial_{\xi_3} \partial_{\xi_2}$$

$$-\xi_2 \partial_{\xi_1} \partial_{\xi_2} - \xi_3 \partial_{\xi_1} \partial_{\xi_3} \cdot (\xi_1^{n_1} \xi_2^{n_2} \xi_3^{n_3} \xi_4^{n_4} \xi_5^{n_5}) \cdot v_\lambda,$$

where $\partial_i$ is short notation for the differential operator $\frac{\partial}{\partial x_i}$, $i = 1, \ldots, 5$. Let $P(\lambda)$ denote the differential operator on $\mathbb{C}[\xi_1, \xi_2, \xi_3, \xi_4, \xi_5]$ obtained in the following
The operator $P(\lambda)$ is homogeneous with respect to the grading in $\mathbb{N}$, and its application to a homogeneous polynomial in $u_1 = u_1(\xi_1, \ldots, \xi_5)$, $u_2 = u_2(\xi_1, \ldots, \xi_5)$ yields

$$P(\lambda)(\sum_{k=0}^{N} A_k u_2^k u_2^{N-k}) = \sum_{k=0}^{N} A_k (2(N-k)k(2(N-k)-1)\xi_4 + 2\xi_3 u_1 u_2^{N-k-1} + k((-k-2(N-k) + \lambda + 2)\xi_4 - \xi_3 u_1) u_2^{N-k-1})$$

$$= \sum_{s=1}^{N} k A_{s-1}(N-(s-1))(2(N-(s-1))-1)\xi_4 + 2\xi_3 u_1 u_2^{N-s-1} + s\xi_3 u_1 u_2^{N-s-1} + k((-k-2(N-k) + \lambda + 2)\xi_4 - \xi_3 u_1) u_2^{N-s-1})$$

$$= \sum_{s=1}^{N} (2A_{s-1}(N-s+1)((2N-2s+1)\xi_4 + 2\xi_3 u_1) + sA_s((s-2N+\lambda + 2)\xi_4 - \xi_3 u_1) u_2^{N-s-1} + k((-k-2(N-k) + \lambda + 2)\xi_4 - \xi_3 u_1) u_2^{N-s-1})$$

The $2N$ summands of the form $\xi_4 u_1^{s-1} u_2^{N-s}$ and $\xi_3 u_1 u_2^{N-s}$ are linearly independent and therefore the above sum is zero if and only if

$$2A_{s-1}(N-s+1)((2N-2s+1)\xi_4 + 2\xi_3 u_1) + sA_s((s-2N+\lambda + 2)\xi_4 - \xi_3 u_1) = 0.$$

This completes the proof of the theorem.
equals zero for all values of \( s \). When \( s = N \), the above sum becomes
\[
2A_{N-1}(\xi_4 + 2\xi_3\xi_5) + N\lambda((-N + \lambda + 2)\xi_4 - \xi_3\xi_5) = 0.
\]
It is a straightforward check that if \( A_N \) vanishes, then \( A_{N-1}, A_{N-2}, \ldots \) must also vanish; therefore we may assume \( A_N \neq 0 \). The vanishing of the coefficient in front of \( \xi_4 \) implies \( A_{N-1} = -\frac{1}{2}NA_N(-N + \lambda + 2) \) and in turn, the vanishing of the coefficient in front of \( \xi_3\xi_5 \) implies \(-5 + 2N - 2\lambda = 0\). Therefore
\[
\lambda = N - 5/2.
\]
Substituting \( \lambda \) back into (14), we get
\[
2A_{N-1}(N - s + 1)((2N - 2s + 1)\xi_4 + 2\xi_5\xi_3) + sA_s((-N + s - 1/2)\xi_4 - \xi_3\xi_5) = 0.
\]
This implies \( A_s = \frac{4(N-s+1)}{s}A_{s-1} = \cdots = 4^s(N_s)A_0 \), which completes the proof of 1).

2. A \( i(\text{Lie } G_2) \cap p \)-singular vector is, in particular, \( sl(2) \simeq i([l', l']) \)-singular and by Lemma 4.1 must be of the form \( u = \xi_3 \sum_{k=0}^{N} A_k u_1^k u^{N-k}_2 \). The application of \( 2\xi_5 \partial_3 \) converts \( A_N(\xi_1\xi_4 + \xi_2\xi_5)^N\xi_3 \) into \( 2A_N(\xi_1\xi_4 + \xi_2\xi_5)^N\xi_5 \). Furthermore \( A_N(\xi_1\xi_4 + \xi_2\xi_5)^N\xi_5 \) contains in its binomial expansion \( 2A_N(\xi_1\xi_4)^N\xi_3 \). Direct check shows that the action of \( P(\lambda) \) on \( (\xi_1\xi_4 + \xi_2\xi_5)^N - \xi_3^{1+2i} \) for \( i > 0 \) does not contain the monomial \((\xi_1\xi_4)^N\xi_5 \). This implies that \( A_N = 0 \) and by induction, the polynomial is trivial. Consequently, there is no nontrivial odd homogeneity polynomial solving the differential equation \( P(\lambda) \).

As an illustration, for \( N = 0 \) we have \( P(\lambda)(A_0\xi_3) = 2A_0\xi_5 \). This vanishes provided \( A_0 = 0 \), which implies the polynomial is trivial.

3. An \( so(7) \cap p \)-singular vector must be \( i(\text{Lie } G_2) \cap p \)-singular. From 1) we know that there is at most one \( i(\text{Lie } G_2) \cap p \)-singular vector. The simple part of \( l \) is isomorphic to \( so(5) \) and induces the quadratic form with matrix in the coordinates \( \xi_1, \ldots, \xi_5 \)
\[
Q = \begin{pmatrix}
0 & 0 & 0 & 0 & 2 \\
0 & 0 & 0 & 0 & 2 \\
0 & 0 & 1 & 0 & 0 \\
2 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 & 0
\end{pmatrix},
\]
i.e., the metric of the form
\[
g(\xi_1, \xi_2, \xi_3, \xi_4, \xi_5) = (d\xi_3)^2 + 2(d\xi_1 \otimes d\xi_4 + d\xi_4 \otimes d\xi_1) + 2(d\xi_2 \otimes d\xi_5 + d\xi_5 \otimes d\xi_2).
\]
The Fourier transform of the \( so(5) \)-invariant Laplace operator associated to \( Q \) is
\[
\mathcal{F}(\triangle_\xi) = Q(\xi_1, \xi_2, \xi_3, \xi_4, \xi_5) = 4(\xi_1\xi_4 + \xi_2\xi_5) + \xi_3^2.
\]
Relying on \( \Delta_\xi \) and the binomial formula for \((4(\xi_1\xi_4 + \xi_2\xi_5) + \xi_3^2)^s \), we see that the Lie \( G_2 \cap p \)-singular vector constructed 1) is indeed \( so(7) \cap p \)-singular. The proof is complete. □
We note that an alternative proof of 3) can be given as follows. From a well known example (see e.g., [3], [10], [11]) of singular vectors in conformal geometry of dimension 5 describing conformally invariant powers of the Laplace operator, we know that for \( \lambda \in \{-3/2, -1/2, 1/2, \ldots\} \) there exists one \( \mathfrak{so}(7) \cap \mathfrak{p} \)-singular vector in \( M^{\mathfrak{so}(7)}_{\mathfrak{p}(1,0,0)}(C_\lambda) \). On the other hand points 1) and 2) of Theorem 4.2 present us with only one such candidate, so that candidate must be the \( \mathfrak{so}(7) \cap \mathfrak{p} \)-singular vector in question.

For \( \lambda \in \{-3/2, -1/2, 1/2, \ldots\} \), the \( \mathfrak{h} \)-weight of the \( \mathfrak{so}(7) \cap \mathfrak{p} \)-singular vector in \( M^{\mathfrak{so}(7)}_{\mathfrak{p}(1,0,0)}(C_\lambda) \) given by Theorem 4.2 equals \( (\lambda - 2N)\varepsilon_1 = (\lambda - 2(\lambda + 5/2))\varepsilon_1 = (-\lambda - 5)\varepsilon_1 \). Therefore the vector from Theorem 4.2 corresponds to the homomorphism of generalized Verma modules

\[
M^{\mathfrak{so}(7)}_{\mathfrak{p}(1,0,0)}(C_\lambda) \hookrightarrow M^{\mathfrak{so}(7)}_{\mathfrak{p}(1,0,0)}(C_{-\lambda - 5}). \tag{15}
\]

In an analogous fashion we conclude that Theorem 4.2 gives a homomorphism of generalized Verma modules

\[
M^{\text{Lie } G_2}_{\mathfrak{p}'(1,0)}(\mathbb{V}_\lambda \psi_1) \rightarrow M^{\text{Lie } G_2}_{\mathfrak{p}'(1,0)}(C_{(-\lambda - 5)} \psi_1). \tag{16}
\]

We conclude this paper with the following observation from [14], a proof of which we include for completeness.

**Proposition 4.3** Suppose \( \lambda \in \{-3/2, -1/2, 1/2, \ldots\} \). Then both (15) and (16) are non-standard homomorphisms.

**Proof.** 1. Let \( \rho_l \) be the half-sum of the positive roots of \( \mathfrak{l} \), i.e., \( \rho_l := 3/2\varepsilon_2 + 1/2\varepsilon_3 \), and let \( s_{\eta_3} \) denote the reflection with respect to the simple root \( \eta_3 = \varepsilon_3 \). Then

\[
s_{\eta_3}(\lambda \varepsilon_1 + \rho_l) - ((-\lambda - 5)\varepsilon_1 + \rho_l) = (2\lambda + 5)\varepsilon_1 - \varepsilon_3. \tag{17}
\]

As \( \lambda \in \{-3/2, -1/2, 1/2, \ldots\} \), the expression (17) is a sum of positive roots of \( \mathfrak{so}(7) \). Therefore by [2] Chapter 7 the non-generalized Verma module with highest weight \((-\lambda - 5)\varepsilon_1 + \rho_l \) lies in the non-generalized Verma module with highest weight \( s_{\eta_3}(\lambda \varepsilon_1 + \rho_l) \). Therefore by [13] Proposition 3.3] the homomorphism (15) is non-standard.

2. Let \( \rho_{v} = 1/2\alpha_2 \). Let \( s_{\alpha_2} \) denote the reflection with respect to the simple root \( \alpha_2 \) (in \( \mathfrak{h}^* \)). Then

\[
s_{\alpha_2}(\lambda \psi_1 + \rho_v) - ((-5 - \lambda)\psi_1 + \rho_v) = (2\lambda + 6)\alpha_2 + (4\lambda + 16)\alpha_1
\]

is clearly a positive integral combination of positive roots of \( \text{Lie } G_2 \) and the statement follows again by [2] Chapter 7 and [13] Proposition 3.3. \( \square \)
